

INSTRUCTIONS FOR AMATEUR OBSERVERS

The Juno mission science team strongly encourages mission-supporting observations from both the professional and amateur communities. We are scheduling a beta test for imaging contributions from the amateur community with a point of deposit on the Mission Juno website that will go live on April 28, 2015. Image files can be uploaded onto that site, including those from earlier in the year (e.g the epoch around Jupiter opposition in early February). Files can be uploaded through May 26, 2015, after which we will assess our ability to work with the data, organizing them and transforming them into a form most useful for the Juno science team.

For the purpose of this test, we're asking for only a sample of your data for one or two observing sessions. This is simply to be sure that we can process your images in the format in which you prefer to send them and to iron out any difficulties you have in transmitting them. This will enable us to incorporate all your images efficiently and with minimal difficulties when we open up for all of your contributions this fall.

We will accept data in any form and using any filters that are available to each contributor.

We note that images that will be most valuable for us should not be in a destructively compressed format. If at all possible, render them in TIF or PNG (or FITS) formats that preserve the linearity of the detector response. JPEG or GIF formats destroy the linearity, so please avoid these.

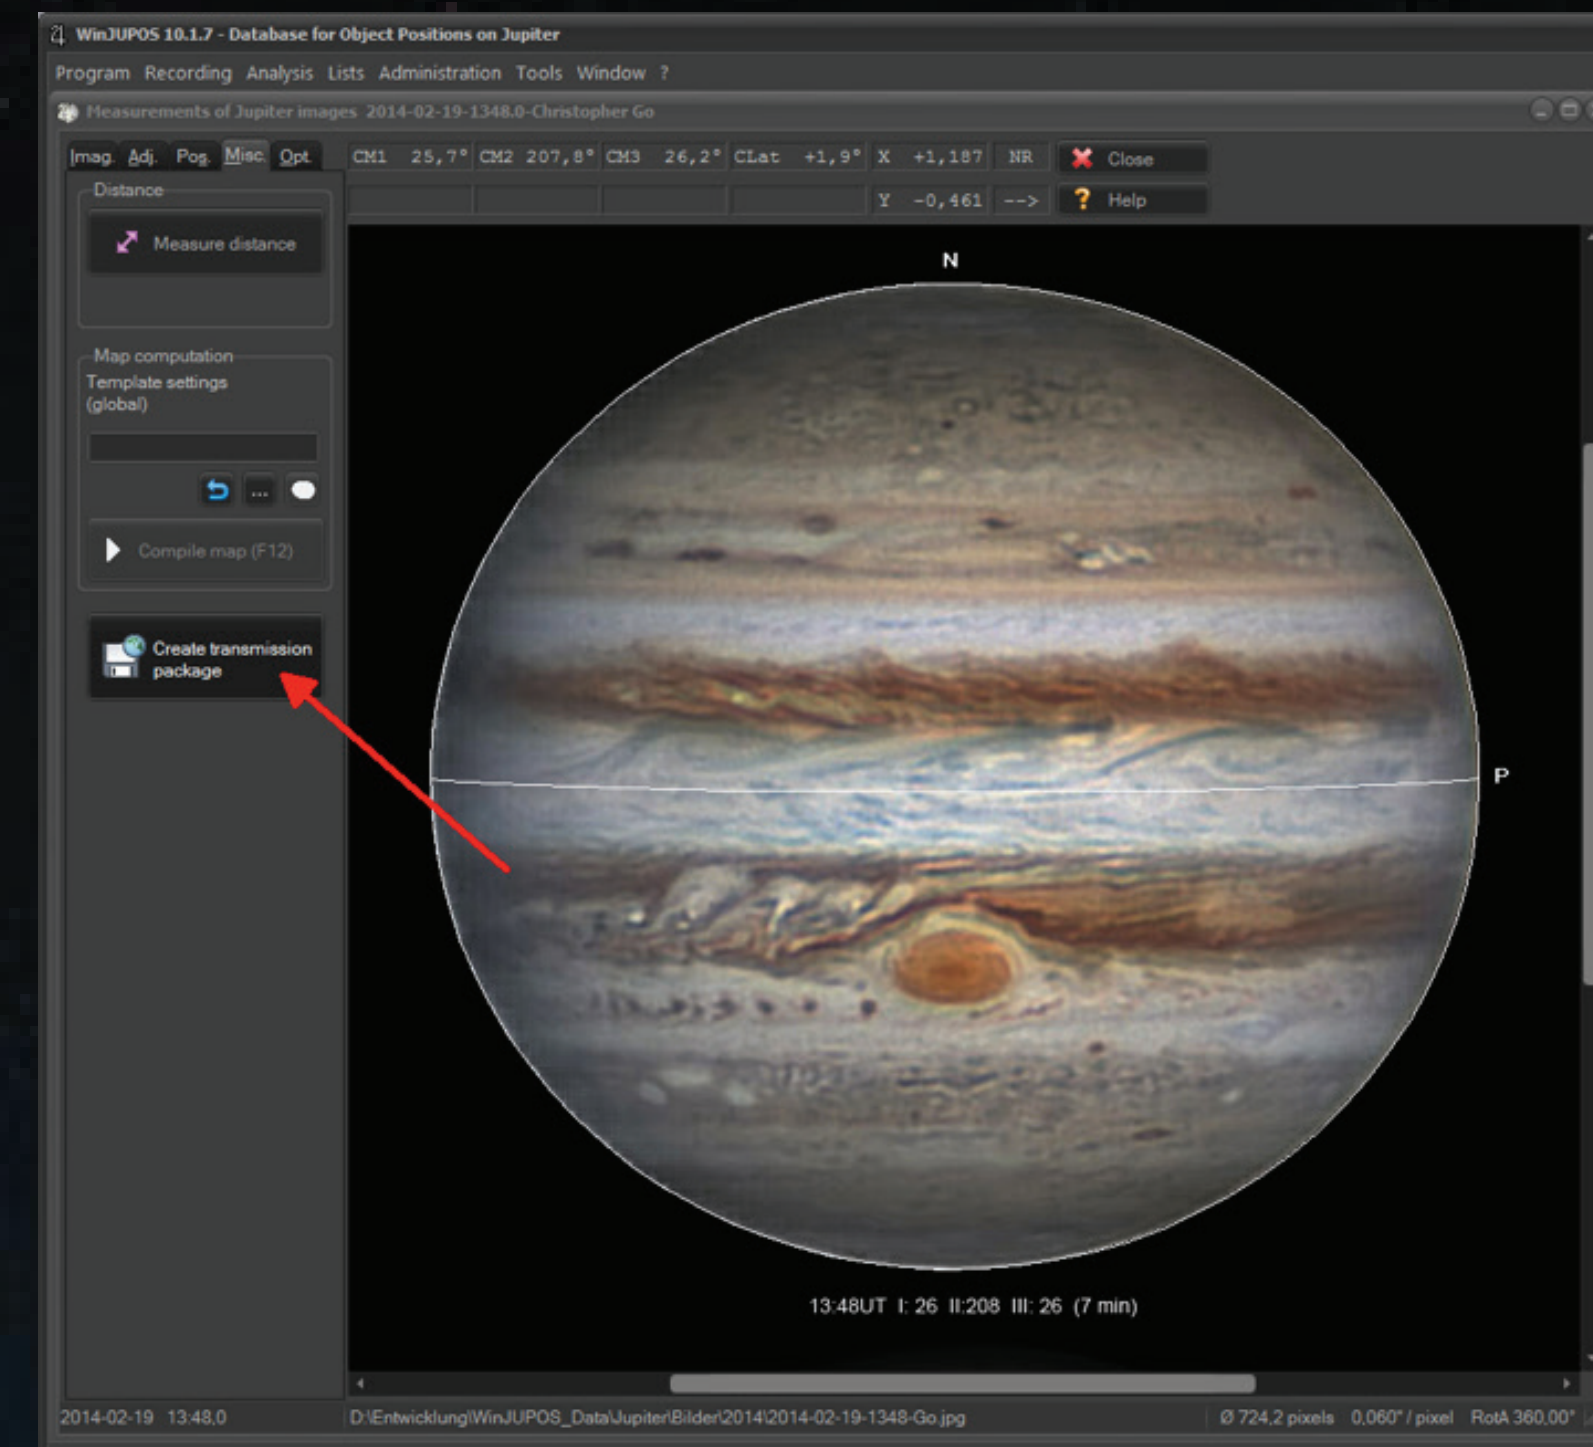

Send us the information on who made the image, where it was made, what date and time, and which filter was used or whether a color camera was used.

Send us a "sharpened" image, if you wish, but we request also an image that has not been subject to any processing. This will make it easier for us to use the same approach on several different types of images during the same epoch.

Our preferred approach is for you to use the WinJUPOS freeware that is maintained and distributed by the JUPOS planetary tracking group of amateur astronomers in Germany. Download from: jupos.privat.t-online.de. All of the information we need can be made available through this software. The information on the circumstances under which the image was taken will be added to an “eml” file. You can use the program to make longitude-latitude maps from each image, which is extremely helpful to us, saving us much time. The current version of WinJUPOS also makes it easy to bundle and compress all the files, making it easy to deposit everything in a single zipped package, using the “Create transmission package” module in the menu list (see the figure right).

So WinJUPOS users should:

- Start the “Recording/Image measurement” module
- Load the image
- Adjust the outline frame to match Jupiter’s limb
- Save the settings
- Where possible, ensure that North is facing up
- Please use the following preferred naming convention: YYYYMMDD_HHMMSS
- Call the “Create transmission package”
- Upload the file to the Juno site: <https://www.missionjuno.swri.edu/junocam/planning>

If you are not new to imaging Jupiter but don't use this approach yet, you might try making very sharp images by the "lucky imaging" technique, using a video to capture several hundred images of Jupiter in any given filter. These are then loaded into software that selects the crispest images and then coadds them, shifting each exposure around, as necessary, to register them properly. Two types of freeware are available to do this type of processing: (i) Autostakkert is described in and can be downloaded from: autostakkert.com, (ii) Registax is described in and can be downloaded from: astronomie.be/registax. If you use these programs, please turn off the histogram stretching before registering and stacking the images.

An introduction to making high-quality planetary images by prominent amateur astronomer Christopher Go (Cebu City, Philippines) is given in this power-point presentation.

High Resolution Planetary Imaging

A splendid exposition of planetary imaging by prominent amateur Damian Peach is available as a chapter in the book "Lessons from the Masters – Current Concepts in Astronomical Image Processing", edited by Robert Gendler, available here:

Lessons from the Masters – Current Concepts in Astronomical Image Processing

Damian also has a great tutorial on DVD, "High-Resolution Astrophotography".

damianpeach.com/dvd.htm

Questions can be directed to Juno scientist Glenn Orton (glenn.orton@jpl.nasa.gov), who is responsible for coordinating all Earth-based supporting observations for the Juno mission.
